

RUNBOOK — Fly GACA iOS apps (native family + store presence)

SECTION 06-operations-it

TYPE runbook

STATUS **active**

OWNER Founder

UPDATED 2026-08-19

Current track. The shipping iOS strategy is the **native app family** — one offline SwiftUI app per study module, paid up-front, built from `ay2m/FlyGACA-ios` (a shared `FlyGACAKit` package plus one app target per module, with per-app content snapshots synced from the web monorepo). The single-app **Capacitor + subscription** wrapper this runbook originally documented is retired — see the note at the end.

[!IMPORTANT] iOS is `ay2m/FlyGACA-ios`, **not** `ay2m/FlyGACA`. `ay2m/FlyGACA` is the web app and its Express backend; it is the **content** source of truth (the corpus, `src/lib/prepCatalog.ts`, the content and icon generators) but holds no Swift. Earlier versions of this page named the wrong repo.

0. The native app family — release path

What ships: two independent App Store apps — ELPT and AIP (bundle ids `com.flygaca.<module>`), sold together via an App Store app bundle. Identical offline feature set: study mode, quizzing, flashcards with spaced repetition, mock tests, and a timed scored exam simulation. **No accounts, no IAP, no network in v1** — content is bundled at build time.

The licence-exam modules (**PPL, CPL, IR, ATPL**) were **paused on 2026-08-10** and their targets removed from the repo. They exist in git history; their **web** study packs are untouched and still selling. Do not "fix" a doc by restoring a six-app list.

The operational detail lives with the code — this section only points at it:

1. **Content sync** — `scripts/sync-content.sh` in `ay2m/FlyGACA-ios`, run against a clone of `ay2m/FlyGACA`. The web repo stays the corpus source of truth; the sync only ever runs monorepo → iOS repo, never the reverse.
2. **Build / test / CI** — `docs/RUNBOOK-ios-release.md` and `.github/workflows/ios.yml` in the iOS repo: Swift tests, XcodeGen validation, a per-app build matrix, and a TestFlight lane that activates once signing secrets exist. `docs/RUNBOOK-ios-xcodebuild.md` covers local builds.
3. **Apple portal (human, one-time)** — `docs/RUNBOOK-ios-signing.md` + `docs/RUNBOOK-ios-signing-CHECKLIST.md`, with `docs/PORTAL-RUNSHEET-wave1.md` as the run sheet: App Group `group.com.flygaca.study`; App IDs (Sign in with Apple was **removed** from the shared entitlements in 2026-08); distribution certificate; `FlyGACA <APP> AppStore` provisioning profiles; paid App Store Connect records; the ASC API key; then the GitHub signing secrets (`scripts/native/set-signing-secrets.sh`).

- 4. **Corpus signing** — `docs/CORPUS-SIGNING.md` (Ed25519) for the remote quiz corpus.
- 5. **Store listings** — per-app EN + AR copy and screenshots. Listing copy describes the offline, English-language app truthfully.

Apple review checklist — native offline v1

- **No IAP and no external purchase links** — the apps are paid up-front, so guideline 3.1.1 does not apply.
- **No account system in v1** — Sign in with Apple (4.8) and in-app account/data deletion (5.1.1) become requirements only if an online phase ships sign-in.
- **Privacy nutrition labels:** "Data Not Collected" (offline; no analytics, no tracking). Revisit before any telemetry is ever added.
- **The "not for operational use" disclaimer stays prominent** in every app and listing — educational use only; GACA is always the authority.
- **Guideline 4.3(b) (spam/app farms)** — sibling apps from one shell: keep the differentiation dossier ready before submission.

If an online phase is ever added

The apps are offline by design and nothing below is scheduled. If sign-in, sync or purchases are added later, they go through **the same backend the web app uses** — the Express service on Cloud Run, with Cloud SQL behind it, sessions as an HttpOnly JWT cookie, and entitlements written only by the server's billing and grants routes. See `../hosting-facts.md`.

[!WARNING] **There is no Firebase in this product.** Any step that says "add an iOS app to the `flygaca-app` Firebase project", "download `GoogleService-Info.plist`", or "enable the Firebase Auth Apple provider" is retired — those projects are deleted. `ay2m/FlyGACA-ios` still carries a `docs/RUNBOOK-ios-firebase.md` written for that plan; it is stale and needs retiring in its own repo (flagged, not fixed from here).

If the subscription wrapper is ever revived, note two things:

- The Capacitor shell and its native bridge still exist in `ay2m/FlyGACA` (`capacitor.config.ts` , `src/lib/native/nativeBridge.ts`) — inert on web, routing auth/IAP/offline-cache through Capacitor plugins inside a native shell. That is the mechanism; **RevenueCat and Stripe are not** — both are gone, and web payments are Moyasar.
- **App Store prices must mirror the current web prices**, not the 2026 draft ones. Today: Pro **SAR 79/month · 649/year**; Exam Season Pass **SAR 299 / 90 days**; exam-prep packs banded **SAR 249 / 399 / 499**; the pack bundle **SAR 1,499**; a chat credit pack **SAR 39**. There is **no Student tier**. Apple's cut makes the in-app price a commercial decision, not a copy of the web number — take it deliberately, and remember rule 3.1.1 forbids the app pointing at web checkout.

Retired — the single Capacitor app + RevenueCat/Stripe subscription track

[!WARNING] **Retired 2026-08-19.** The pre-2026-08 plan (one `com.flygaca.app` Capacitor shell around the web PWA, monetised through RevenueCat and Apple IAP, with entitlements written by a Firebase Cloud Function into Firestore, and web billing through Stripe) documented a stack that no longer exists — Firebase Auth, Firestore, Cloud Functions, `firebase.json`, RevenueCat webhooks and Stripe are all gone. The step-by-step procedure has been removed rather than rewritten, because every command in it would have to be invented.

What survives conceptually is captured above: the native family is the launch path, and any future subscription wrapper builds on the Cloud Run API. B2B school licences are handled today by the product's own grants routes and the org-admin dashboard — see the B2B design docs in `ay2m/FLyGACA` `docs/b2b/`.
