

Fly GACA — Design Tokens (Tokens Studio import)

SECTION 11-brand TYPE readme STATUS **active** OWNER Founder UPDATED 2026-06-16

Extracted from `flygaca/assets/css/tokens.css` + `base.css`. Import into Figma with the **Tokens Studio** plugin (free) — no Figma MCP limits involved.

What's in the file

`flygaca-design-tokens.json` — 130 tokens across 8 sets:

Set	Tokens	Notes
<code>primitives</code>	Falcon palette, amber, status, ink (dark text), paper (light neutrals)	raw values; referenced, not themed
<code>spacing</code>	<code>space.1</code> – <code>space.16</code>	4px base, in px
<code>radius</code>	sm/md/lg/xl/pill	
<code>typography</code>	font, weight, size, line-height, tracking	sizes are the desktop upper bound of the CSS <code>clamp()</code> scale
<code>text</code>	display, h1–h3, lead, body, small, eyebrow, mono-label	composite type styles → become Figma text styles
<code>shadow</code>	sm, card, pop, amber, amber-strong	→ Figma effect styles
<code>color-dark</code>	full semantic set	extracted from code (dark-first)
<code>color-light</code>	full semantic set	newly authored light theme

Two themes are defined — **Dark** and **Light** — under a `mode` group. Each enables its own color set and shares the primitives, scale, type, and shadow sets.

How to import

1. In Figma, install **Tokens Studio for Figma** (Plugins → find more → "Tokens Studio").
2. Open it → **Settings** → use "Single file", or just **Tools** → **Import** → **Import from file** and select `flygaca-design-tokens.json`.
3. Tokens Studio loads all 8 sets and both themes.
4. Open the **Themes** dropdown → for each theme (Dark, Light) click **Export to Figma** (or "Create variables"). This generates real Figma variable collections + modes, plus text and effect styles.

5. The `$figmaCollectionId` / `$figmaModeId` fields are left null on purpose — Tokens Studio fills them on first export so re-imports update in place instead of duplicating.

After export you'll have native Figma variables (with Light/Dark modes on the color collection), text styles, and effect styles — exactly the Phase 1 foundation, just created by the plugin instead of the MCP.

Decisions baked in (from discovery)

- **Primary CTA = amber** `#FFB020` (`color.primary`), brand fill = teal (`color.brand`). This matches the live `.btn-primary`, which is amber despite `--brand` being teal.
- **Light mode is net-new.** Code is dark-only; the `color-light` set is an authored light theme using the same palette. Light `link` / `accent` / `danger-text` use darker primitives (`teal-deep`, `sage-deep`, `danger-deep`) added for WCAG contrast on white.
- **Off-palette values folded in** as primitives: `palette.amber`, `palette.amber-bright`, `palette.amber-ink` (`#0A0E14`).

Resuming the native Figma build

When the Figma plan limit lifts (or you upgrade), I can resume the original MCP build — components with variants and variable bindings (Button, Field, Card, Chip, Nav, Footer) — using the saved state. This token JSON and that build target the same file, so they're compatible.
