

Runbook — Deploy Fly GACA to Firebase Hosting

SECTION 06-operations-it

TYPE runbook

STATUS **active**

OWNER Founder

UPDATED 2026-06-16

The Phase 1 site (landing, library, reader, aerodrome dashboard + map, chart viewer, legal pages) is built. This runbook takes it live on `flygaca.com`.

Good news: Firebase Hosting works on the **free Spark plan** — no Blaze upgrade or payment card is needed to deploy. (Blaze is only needed later, for Phase 2's Cloud Functions.)

What deploys: the HTML pages, `assets/` (CSS, JS, fonts, images, and the generated `assets/data/` catalogues, part text and chart images), `sw.js` and the manifest. The raw corpus in `library/` is excluded by `firebase.json`, so the ~1 GB of source PDFs never uploads.

One-time setup

1. **Install the Firebase CLI** (needs Node.js, already on your machine):

```
npm install -g firebase-tools
```

2. **Sign in** with the Google account that owns the Firebase project (`flygaca@gmail.com`):

```
firebase login
```

The repo already contains `firebase.json` (hosting config) and `.firebaserc` (which points at the `flygaca-firebase` project), so there is nothing else to configure.

Deploy

From the repository root:

```
cd ~/Documents/Claude/flygaca/flygaca
firebase deploy --only hosting
```

When it finishes, the CLI prints a **Hosting URL** — `https://flygaca-firebase.web.app`. Open it: the full site is live over HTTPS, and everything that needs HTTP (the library, the reader, the map, the chart viewer) now works.

Connect the custom domain — flygaca.com

1. Firebase Console → your project → **Hosting** → **Add custom domain**.
 2. Enter `flygaca.com`.
 3. Firebase gives you DNS records (an A record, or TXT for verification). Add them at your domain registrar.
 4. Firebase provisions an SSL certificate automatically (can take up to ~24 h).
-

Updating the site later

Re-run `firebase deploy --only hosting` after any change. When you change site code, **bump** `VERSION` in `sw.js` (e.g. `flygaca-v1` → `flygaca-v2`) so returning visitors pick up the update rather than a stale cached copy.

Optional — automatic deploys: a GitHub Actions workflow can deploy on every push to `main`. It needs a Firebase CI token or service account stored as a GitHub secret. Set this up once the manual deploy is confirmed working.

Pre-launch reminders

- The **legal pages are drafts** — have the Saudi lawyer review the Terms, Privacy Notice and Disclaimer before the site is publicly announced (see `office/lawyer-brief.md`).
- Create the contact mailboxes referenced on the site: `i@flygaca.com` and `info@flygaca.com`.
- The library now hosts GACAR text and AIP-derived material — the redistribution position (P0-1) should be confirmed by the lawyer.
